exercise 03 notebook

November 1, 2019

1 Programming assignment 3: Probabilistic Inference

```
[1]: import numpy as np
  import matplotlib.pyplot as plt

from scipy.special import loggamma
  %matplotlib inline
```

1.1 Your task

This notebook contains code implementing the methods discussed in Lecture 3: Probabilistic Inference. Some functions in this notebook are incomplete. Your task is to fill in the missing code and run the entire notebook.

In the beginning of every function there is docstring, which specifies the format of input and output. Write your code in a way that adheres to it. You may only use plain python and numpy functions (i.e. no scikit-learn classifiers).

1.2 Exporting the results to PDF

Once you complete the assignments, export the entire notebook as PDF and attach it to your homework solutions. The best way of doing that is 1. Run all the cells of the notebook. 2. Export/download the notebook as PDF (File -> Download as -> PDF via LaTeX (.pdf)). 3. Concatenate your solutions for other tasks with the output of Step 2. On a Linux machine you can simply use pdfunite, there are similar tools for other platforms too. You can only upload a single PDF file to Moodle.

Make sure you are using nbconvert Version 5.5 or later by running jupyter nbconvert --version. Older versions clip lines that exceed page width, which makes your code harder to grade.

1.3 Simulating data

The following function simulates flipping a biased coin.

```
[2]: # This function is given, nothing to do here.

def simulate_data(num_samples, tails_proba):
    """Simulate a sequence of i.i.d. coin flips.

Tails are denoted as 1 and heads are denoted as 0.

Parameters
------
num_samples : int
    Number of samples to generate.
tails_proba : float in range (0, 1)
    Probability of observing tails.

Returns
-----
samples : array, shape (num_samples)
    Outcomes of simulated coin flips. Tails is 1 and heads is 0.
"""
return np.random.choice([0, 1], size=(num_samples), p=[1 - tails_proba, □
→tails_proba])
```

```
[3]: np.random.seed(123) # for reproducibility
num_samples = 20
tails_proba = 0.7
samples = simulate_data(num_samples, tails_proba)
print(samples)
```

 $[1\ 0\ 0\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 0\ 1\ 1\ 0\ 0\ 1\ 1]$

2 Important: Numerical stability

When dealing with probabilities, we often encounter extremely small numbers. Because of limited floating point precision, directly manipulating such small numbers can lead to serious numerical issues, such as overflows and underflows. Therefore, we usually work in the **log-space**.

For example, if we want to multiply two tiny numbers a and b, we should compute $\exp(\log(a) + \log(b))$ instead of naively multiplying $a \cdot b$.

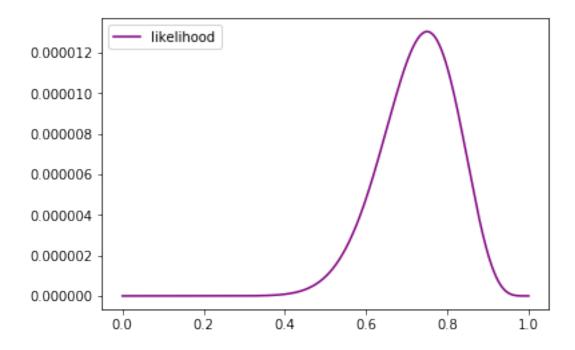

For this reason, we usually compute **log-probabilities** instead of **probabilities**. Virtually all machine learning libraries are dealing with log-probabilities instead of probabilities (e.g. Tensorflow-probability or Pyro).

2.1 Task 1: Compute $\log p(\mathcal{D} \mid \theta)$ for different values of θ

```
[4]: def compute_log_likelihood(theta, samples):
         """Compute log p(D \mid theta) for the given values of theta.
         Parameters
         _____
         theta : array, shape (num_points)
             Values of theta for which it's necessary to evaluate the log-likelihood.
         samples : array, shape (num_samples)
             Outcomes of simulated coin flips. Tails is 1 and heads is 0.
         Returns
         ____
         log_likelihood : array, shape (num_points)
             Values of log-likelihood for each value in theta.
         11 11 11
         ### YOUR CODE HERE ###
         tails = (samples==1).sum()
         heads = (samples==0).sum()
         log_likelihood = (tails * np.log(theta)) + (heads * np.log(1-theta))
         return log_likelihood
     log_likelihood = compute_log_likelihood(x, samples)
```

```
[5]: x = np.linspace(1e-5, 1-1e-5, 1000)
log_likelihood = compute_log_likelihood(x, samples)
likelihood = np.exp(log_likelihood)
plt.plot(x, likelihood, label='likelihood', c='purple')
plt.legend()
```

[5]: <matplotlib.legend.Legend at 0x7f31e8559f50>

Note that the likelihood function doesn't define a probability distribution over θ — the integral $\int_0^1 p(\mathcal{D} \mid \theta) d\theta$ is not equal to one.

To show this, we approximate $\int_0^1 p(\mathcal{D} \mid \theta) d\theta$ numerically using the rectangle rule.

```
[6]: # 1.0 is the length of the interval over which we are integrating p(D / theta)
int_likelihood = 1.0 * np.mean(likelihood)
print(f'Integral = {int_likelihood:.4}')
```

Integral = 3.068e-06

2.2 Task 2: Compute $\log p(\theta \mid a, b)$ for different values of θ

The function loggamma from the scipy.special package might be useful here. (It's already imported - see the first cell)

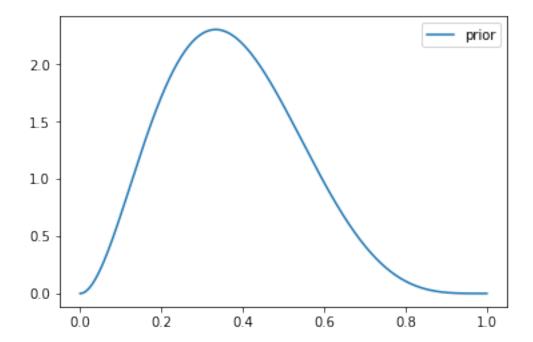

```
[7]: def compute_log_prior(theta, a, b):
    """Compute log p(theta | a, b) for the given values of theta.

Parameters
-----
theta: array, shape (num_points)
    Values of theta for which it's necessary to evaluate the log-prior.
    a, b: float
    Parameters of the prior Beta distribution.
```

```
[8]: x = np.linspace(1e-5, 1-1e-5, 1000)
a, b = 3, 5

# Plot the prior distribution
log_prior = compute_log_prior(x, a, b)
prior = np.exp(log_prior)
plt.plot(x, prior, label='prior')
plt.legend()
```

[8]: <matplotlib.legend.Legend at 0x7f31e81e9d10>

Unlike the likelihood, the prior defines a probability distribution over θ and integrates to 1.

```
[9]: int_prior = 1.0 * np.mean(prior)
print(f'Integral = {int_prior:.4}')
```

2.3 Task 3: Compute $\log p(\theta \mid \mathcal{D}, a, b)$ for different values of θ

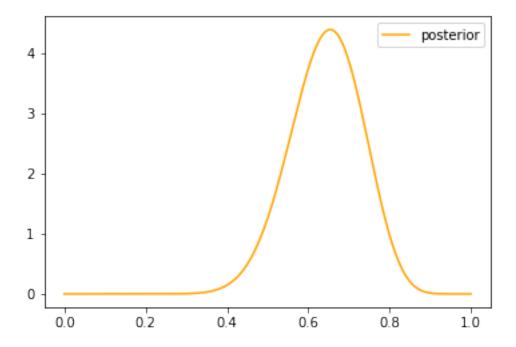

The function loggamma from the scipy.special package might be useful here.

```
[10]: def compute_log_posterior(theta, samples, a, b):
          """Compute log p(theta | D, a, b) for the given values of theta.
          Parameters
          _____
          theta: array, shape (num_points)
              Values of theta for which it's necessary to evaluate the log-prior.
          samples : array, shape (num_samples)
              Outcomes of simulated coin flips. Tails is 1 and heads is 0.
          a, b: float
              Parameters of the prior Beta distribution.
          Returns
          log_posterior : array, shape (num_points)
              Values of log-posterior for each value in theta.
          ### YOUR CODE HERE ###
          log_posterior = (compute_log_likelihood(theta, samples) +_{\sqcup}
       →compute_log_prior(theta,a,b)) - np.log(1.0*np.mean(likelihood*prior))
          return log_posterior
[11]: x = np.linspace(1e-5, 1-1e-5, 1000)
```

```
[11]: x = np.linspace(1e-5, 1-1e-5, 1000)

log_posterior = compute_log_posterior(x, samples, a, b)
posterior = np.exp(log_posterior)
plt.plot(x, posterior, label='posterior', c='orange')
plt.legend()
```

[11]: <matplotlib.legend.Legend at 0x7f31e815f390>

Like the prior, the posterior defines a probability distribution over θ and integrates to 1.

```
[12]: int_posterior = 1.0 * np.mean(posterior)
print(f'Integral = {int_posterior:.4}')
```

Integral = 1.0

2.4 Task 4: Compute θ_{MLE}

```
[13]: def compute_theta_mle(samples):
    """Compute theta_MLE for the given data.

Parameters
-------
samples : array, shape (num_samples)
    Outcomes of simulated coin flips. Tails is 1 and heads is 0.

Returns
------
theta_mle : float
    Maximum likelihood estimate of theta.
"""
### YOUR CODE HERE ###
tails = (samples==1).sum()
heads = (samples==0).sum()
```

```
return tails/(tails + heads)
```

```
[14]: theta_mle = compute_theta_mle(samples)
print(f'theta_mle = {theta_mle:.3f}')
```

theta mle = 0.750

2.5 Task 5: Compute θ_{MAP}

```
[15]: def compute_theta_map(samples, a, b):
          """Compute theta_MAP for the given data.
          Parameters
          samples : array, shape (num_samples)
              Outcomes of simulated coin flips. Tails is 1 and heads is 0.
          a, b: float
              Parameters of the prior Beta distribution.
          Returns
           -----
          theta\_map : float
              Maximum a posteriori estimate of theta.
          11 11 11
          ### YOUR CODE HERE ###
          tails = (samples==1).sum()
          heads = (samples==0).sum()
          theta_map = (tails + a -1)/(tails + heads + a + b -2)
          return theta_map
```

```
[16]: theta_map = compute_theta_map(samples, a, b)
print(f'theta_map = {theta_map:.3f}')
```

 $theta_map = 0.654$

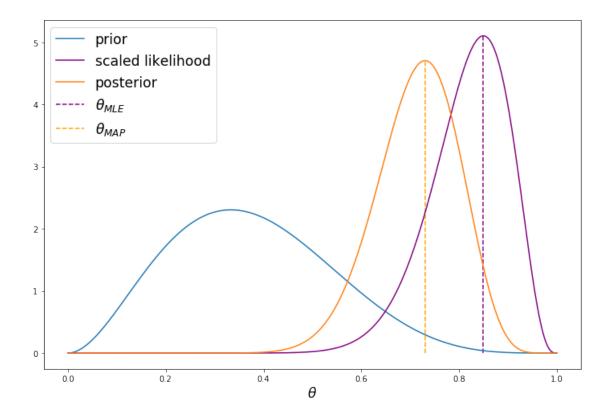

3 Putting everything together

Now you can play around with the values of a, b, num_samples and tails_proba to see how the results are changing.

```
[17]: num_samples = 20
    tails_proba = 0.7
    samples = simulate_data(num_samples, tails_proba)
    a, b = 3, 5
    print(samples)
```

$[1\ 1\ 1\ 1\ 1\ 1\ 1\ 0\ 0\ 1\ 0\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1]$

```
[18]: plt.figure(figsize=[12, 8])
     x = np.linspace(1e-5, 1-1e-5, 1000)
     # Plot the prior distribution
     log_prior = compute_log_prior(x, a, b)
     prior = np.exp(log_prior)
     plt.plot(x, prior, label='prior')
     # Plot the likelihood
     log_likelihood = compute_log_likelihood(x, samples)
     likelihood = np.exp(log_likelihood)
     int_likelihood = np.mean(likelihood)
     # We rescale the likelihood - otherwise it would be impossible to see in the \Box
      \rightarrow plot
     rescaled_likelihood = likelihood / int_likelihood
     plt.plot(x, rescaled_likelihood, label='scaled likelihood', color='purple')
     # Plot the posterior distribution
     log_posterior = compute_log_posterior(x, samples, a, b)
     posterior = np.exp(log_posterior)
     plt.plot(x, posterior, label='posterior')
     # Visualize theta_mle
     theta_mle = compute_theta_mle(samples)
     ymax = np.exp(compute_log_likelihood(np.array([theta_mle]), samples)) /__
      →int likelihood
     plt.vlines(x=theta_mle, ymin=0.00, ymax=ymax, linestyle='dashed',__
      # Visualize theta map
     theta_map = compute_theta_map(samples, a, b)
     ymax = np.exp(compute_log_posterior(np.array([theta_map]), samples, a, b))
     plt.vlines(x=theta_map, ymin=0.00, ymax=ymax, linestyle='dashed',__
      plt.xlabel(r'$\theta$', fontsize='xx-large')
     plt.legend(fontsize='xx-large')
     plt.show()
```
